Interpreting selective-reference evaluation of clearance models

Measured Biogen cohorts: HLM n=929 and RLM n=922 | Fixed RF and XGBoost models

1 Hold probability marginals

Same probabilities; changed pairing

Hajek / CC: 0.883–1.104 original

0.113–0.168 aligned / reversed

Loss-informed oracle diagnostic

2 Trace all original seeds

100 seeds; both observation states

Raw lpc dropped before full refit

Low-P median error: 323.07 → 0.00552

Fixed drug-property models

3 Refit under MW selection

Observable molecular variables only

Low M beats CC: 11/16 settings

Drop lpc beats CC: 10/16 settings

Drop beats low M in only 1/16

Original frozen results retained; new refits and alignment controls are post-result

Check bias strength, feature extrapolation and the uncertainty target separately
